1 Introduction and the Main Theorems

This note describes an algorithm for determining whether a given polynomial $f(x) \in \mathbb{Z}[x]$ has a cyclotomic divisor. In particular, the algorithm works well when the number of non-zero terms is small compared to the degree of $f(x)$. This work is based on a paper by J. H. Conway and A. J. Jones [1]. The specific result we establish is the following.

Theorem 1. *There is an algorithm that has the following property: given* $f(x) = \sum_{j=1}^{N} a_j x^{d_j} \in \mathbb{Z}[x]$ *with* $N > 1$ *and* $\deg f = n > 1$*, the algorithm determines whether* $f(x)$ *has a cyclotomic factor and with running time*

$$\ll \exp\left((2 + o(1))\sqrt{N/\log N}(\log N + \log\log n)\right)\log(H+1) \qquad (1)$$

as N *tends to infinity, where* $H = \max_{1\le j\le N}\{|a_j|\}$.

In the above theorem, we view the input as consisting of a list of N coefficient-exponent pairs (a_j, d_j) sorted in increasing order by the values of d_j. Observe that for fixed N and bounded coefficients, the algorithm runs in time that is polynomial in $\log n$. In the case that a cyclotomic factor exists, the algorithm can be made to output a positive integer m for which $\Phi_m(x)$, the mth cyclotomic polynomial, divides $f(x)$ without affecting the bound given for the running time.

For m a positive integer, let $\zeta_m = e^{2\pi i/m}$. For integers a, b, and m with $m > 0$, we write $a \equiv b \pmod m$ if $m|(a-b)$ and use the notation $a \bmod m$ to represent the unique $b \equiv a \pmod m$ such that $0 \le b < m$. For $f(x)$, $g(x)$, and $w(x)$ in $\mathbb{Q}[x]$ with $\deg w(x) \ge 1$, we write $f(x) \equiv g(x) \pmod{w(x)}$ if $w(x)|(f(x)-g(x))$, and we use the notation $f(x) \bmod w(x)$ to denote the unique polynomial $g(x) \equiv f(x) \pmod{w(x)}$ with either $g(x) \equiv 0$ or $0 \le \deg g(x) < \deg w(x)$. If S is a set, we will denote by $|S|$ the cardinality of S.

Theorem 2. *Let* $f(x) \in \mathbb{Z}[x]$ *have* N *non-zero terms. Suppose* n *is a positive integer such that* $\Phi_n(x)|f(x)$*. Suppose further that* $p_1, p_2, \ldots, p_k$ *are distinct primes satisfying*

$$2 + \sum_{j=1}^{k}(p_j - 2) > N.$$

Let e_j *be the non-negative integer for which* $p_j^{e_j}||n$*. Then for at least one* $j \in \{1, 2, \ldots, k\}$*, we have* $\Phi_m(x)|f(x)$ *where* $m = n/p_j^{e_j}$.

Proof. We first describe and then make use of Theorem 5 from [1]. For r a positive integer, define $\gamma(r) = 2 + \sum_{p|r}(p-2)$. Following [1], we call a vanishing sum S minimal if no proper subsum of S vanishes. We will be interested in sums $S = \sum_{j=1}^{t} a_j\omega_j$ where t is a positive integer, each a_j is a non-zero rational number and each ω_j is a root of unity. We refer to the reduced exponent of such an S as the least positive integer r for which $(\omega_i/\omega_1)^r = 1$ for all $i \in \{1, 2, \ldots, t\}$. Theorem 5 of [1] asserts then that if $S = \sum_{j=1}^{t} a_j\omega_j$ is a minimal vanishing sum, then $t \geq \gamma(r)$ where r is the reduced exponent of S. (Also, note that Theorem 5 of [1] implies that the reduced exponent r of a minimal vanishing sum is necessarily squarefree.)

To prove Theorem 2, we suppose as we may that $e_j > 0$ for each $j \in \{1, 2, \ldots, k\}$. We write $f(x) = \sum_{i=1}^{s} f_i(x)$ where each $f_i(x)$ is a non-zero polynomial divisible by $\Phi_n(x)$, no two $f_i(x)$ have terms involving x to the same power, and s is maximal. Thus, each $f_i(\zeta_n)$ is a minimal vanishing sum. For each $i \in \{1, 2, \ldots, s\}$, we write $f_i(x) = x^{b_i} g_i(x^{d_i})$ where b_i and d_i are non-negative integers chosen so that $g_i(0) \neq 0$ and the greatest common divisor of the exponents appearing in $g_i(x)$ is 1. Then $g_i(\zeta_n^{d_i})$ is a minimal vanishing sum with reduced exponent $n/\gcd(n, d_i)$. If t_i denotes the number of non-zero terms of $g_i(x)$, we deduce from Theorem 5 of [1] that

$$\begin{aligned} N = \sum_{i=1}^{s} t_i &\geq \sum_{i=1}^{s} \gamma\left(\frac{n}{\gcd(n, d_i)}\right) \\ &\geq 2s + \sum_{j=1}^{k} (p_j - 2) \left| \left\{ 1 \leq i \leq s : p_j \text{ divides } \frac{n}{\gcd(n, d_i)} \right\} \right|. \end{aligned}$$

The inequality in Theorem 2 implies that at least one of the expressions $|\{1 \leq i \leq s : p_j | (n/\gcd(n, d_i))\}|$ is zero. In other words, for some $j \in \{1, 2, \ldots, k\}$ and every $i \in \{1, 2, \ldots, s\}$, we have $p_j^{e_j} | d_i$. Setting $m = n/p_j^{e_j}$ and $d_i' = d_i/p_j^{e_j}$, we obtain that $g_i(\zeta_m^{d_i'}) = 0$. Since $\gcd(m, p_j) = 1$, $\zeta_m^{p_j^{e_j}}$ is a primitive mth root of unity and we deduce $g_i(\zeta_m^{d_i}) = 0$. As this is true for every $i \in \{1, 2, \ldots, s\}$, we conclude $f(\zeta_m) = 0$, establishing the theorem. □

Corollary 1. *Let $f(x) \in \mathbb{Z}[x]$ have N non-zero terms. If $f(x)$ is divisible by a cyclotomic polynomial, then there is a positive integer m such that*

$$2 + \sum_{p|m} (p-2) \leq N \quad \textit{and} \quad \Phi_m(x) | f(x).$$

The above is a direct consequence of Theorem 2. Observe that it follows easily from Corollary 1 that if $f(x)$ is divisible by a cyclotomic polynomial, then there is a positive integer m such that every prime divisor of m is $\le N$ and $\Phi_m(x)|f(x)$.

2 The Proof of Theorem 1

For the proof of Theorem 1, we will make use of the following preliminary result of independent interest.

Theorem 3. *There is an algorithm that has the following property: given* $f(x) = \sum_{j=1}^{N} a_j x^{d_j} \in \mathbb{Z}[x]$ *with* $\deg f = n > 1$ *and a positive integer* m *together with its factorization* $m = \prod_{j=1}^{s} p_j^{e_j}$ *where* $s \ge 1$*, the* p_j *are distinct primes* $\le M$*, and the* e_j *are positive integers* $\le E$*, the algorithm determines whether* $\Phi_m(x)$ *divides* $f(x)$ *and with running time*

$$\ll (\log n + \log M)^{2+o(1)} + s\big(\log M + \log(E+1)\big) + s2^s N \log(H+1) + s2^s N(s + \log N)\big(s + \log n + \log N\big)^{1+o(1)},$$

as N *tends to infinity, where* $H = \max_{1\le j\le N}\{|a_j|\}$.

In the above theorem, we view the input as consisting of a list of coefficient-exponent pairs (a_j, d_j) sorted in increasing order by the values of d_j and a list of prime-exponent pairs (p_j, e_j) sorted in increasing order by the values of p_j. The total length of the input is

$$\ll \big(\log(H+1) + \log n\big)N + \big(\log M + \log(E+1)\big)s.$$

Observe that in the statement of the theorem, the bound given for the running time of the algorithm exceeds the length of the input. In fact, the term $s\big(\log M + \log(E+1)\big)$ in the theorem exists only because the input needs to be read.

Proof of Theorem 3. We suppose as we may throughout that $N > 1$. We begin with the algorithm and then justify that the algorithm works and has the indicated bound for its running time.

For a polynomial $g(x) \in \mathbb{Z}[x]$, we define $\omega\big(g(x)\big)$ as $g(x)$ mod $(x^m - 1)$. We can view $\omega\big(g(x)\big)$ as the polynomial obtained by reducing the exponents of

$g(x)$ modulo m and combining the terms with like exponents. In other words, if $g(x) = \sum_{j=1}^{T} u_j x^{v_j}$, then

$$\omega\big(g(x)\big) = \sum_{j=1}^{T} u_j x^{(v_j \bmod m)} = \sum_{j=1}^{T'} u'_j x^{v'_j}$$

where $0 \le v'_1 < v'_2 < \cdots < v'_{T'} < m$, $0 \le T' \le T$, and each u'_j is a sum of one or more u_j.

For the moment, suppose that m has already been computed from the prime-exponent pairs (p_j, e_j); the running time for computing m will be discussed later. Given $g(x)$ as an ordered list of coefficient-exponent pairs (u_j, v_j), ordered in increasing order by the size of v_j, we compute $\omega\big(g(x)\big)$ as follows. We compute the complete list of pairs $(u_j, v_j \bmod m)$ in

$$\ll T(\log U) + T\big(\log m + \log V\big)^{1+o(1)}$$

binary operations, where $U = 1 + \max_{1\le j\le T}\{|u_j|\}$ and $V = 1 + \max_{1\le j\le T}\{v_j\}$. Next, we sort the pairs in increasing order according to the values of $v_j \bmod m$ and combine terms of like exponents to form a sorted list of coefficient-exponent pairs (u'_j, v'_j) associated with $\omega\big(g(x)\big)$; this requires

$$\ll T(\log U) + T(\log T)(\log m + \log T)$$

binary operations. Thus, the total number of binary operations to compute $\omega\big(g(x)\big)$ is bounded by

$$\mathcal{O}\Big(T(\log U) + T(\log T)\big(\log m + \log V + \log T\big)^{1+o(1)}\Big).$$

We use the above to describe and justify the running time of the following algorithm.

Algorithm A *(Specific Cyclotomic Factor Test)***:** Given $f(x) = \sum_{j=1}^{N} a_j x^{d_j} \in \mathbb{Z}[x]$ with $\deg f = n > 1$ and $m = \prod_{j=1}^{s} p_j^{e_j}$ as in the statement of the theorem, determine whether $\Phi_m(x)$ divides $f(x)$.

Step A1. *Check the Size of* $\phi(m)$. Check whether

$$\prod_{j=1}^{s} p_j^{e_j-1}(p_j - 1) \le n.$$

If the inequality holds, then proceed to Step A2. Otherwise, output that $\Phi_m(x)$ does not divide $f(x)$.

Step A2. *Reduce Exponents of f Modulo m.* Compute

$$f_0(x) = \omega\big(f(x)\big)$$

where the function ω is defined above.

Step A3. *Multiply By $x^{m/p} - 1$ For Each p Dividing m.* For $j \in \{1, 2, \ldots, s\}$, recursively define

$$f_j(x) = \omega\big(f_{j-1}(x)\big(x^{m/p_j} - 1\big)\big).$$

Step A4. *Check Whether the Final Result is Zero.* Check whether $f_s(x) \equiv 0$. If $f_s(x) \equiv 0$, then output that $\Phi_m(x)$ divides $f(x)$. Otherwise, output that $\Phi_m(x)$ does not divide $f(x)$.

We justify now the correctness of the algorithm. Since the degree of $\Phi_m(x)$ is

$$\phi(m) = \prod_{j=1}^{s} p_j^{e_j - 1}(p_j - 1),$$

if $\phi(m) > n$, then it is impossible for $\Phi_m(x)$ to divide $f(x)$. It remains to consider then the case that $\phi(m) \leq n$. We use that the factorization of $x^m - 1$ into irreducible polynomials over the rationals is given by

$$x^m - 1 = \prod_{d|m} \Phi_d(x).$$

Observe that every divisor d of m with $d \neq m$ divides m/p_j for some $j \in \{1, 2, \ldots, s\}$. Thus, for each such d, $\Phi_d(x)$ divides the polynomial

$$h(x) = \prod_{j=1}^{s} \big(x^{m/p_j} - 1\big).$$

On the other hand, $\Phi_m(x)$ does not divide $h(x)$. We deduce that $h(x)$ is not divisible by $x^m - 1$, but $\Phi_m(x)h(x)$ is. This implies that $\Phi_m(x)$ divides $f(x)$ if and only if $x^m - 1$ divides $f(x)h(x)$. From Steps A2 and A3, we see that $f_s(x)$ is $f(x)h(x)$ mod $(x^m - 1)$. Therefore, $\Phi_m(x)$ divides $f(x)$ if and only if $f_s(x) \equiv 0$. Step A4 and the correctness of the algorithm are justified.

To obtain the bound on the running time of the algorithm, we begin by estimating the amount of time needed to check the inequality in Step A1. We view

this as being done as follows. Set a variable, say A, to be 1. Consider in turn each p_j beginning with $j = 1$ and ending with $j = s$. For each such j, replace the value of A with the value of $A \times p_j$ and do this $e_j - 1$ times. Then replace the value of A with the value of $A \times (p_j - 1)$ before continuing to the next value of j. After each multiplication, check if $A \le n$. Each multiplication will take $\mathcal{O}\big((\log n + \log M)^{1+o(1)}\big)$ binary operations. At most $\mathcal{O}(\log n)$ multiplications are necessary (before obtaining $A > n$). Hence, Step A1 requires

$$\ll (\log n + \log M)^{2+o(1)}$$

binary operations. Observe that further steps in the algorithm are only considered if $\phi(m) \le n$. In particular, $m \le \phi(m)^2 \le n^2$ implies $\log m \le 2 \log n$. We therefore suppose this holds in discussing the remaining steps of the algorithm.

A procedure analogous to that just described for determining whether the inequality in Step A1 holds can be used for computing m (as well as m/p_j) from the list of exponent pairs (p_j, e_j). Given that now $m \le n^2$, computing m (or m/p_j) requires

$$\ll (\log n + \log M)^{2+o(1)}$$

binary operations.

Given the running time analysis for computing $\omega\big(g(x)\big)$, Step A2 takes

$$\ll N \log(H+1) + N(\log N)\big(\log n + \log N\big)^{1+o(1)}$$

binary operations. In Step A3, for $j \in \{1, 2, \dots, s\}$, we first compute the product $f_{j-1}(x)\big(x^{m/p_j} - 1\big)$. This can be done by replacing each coefficient-exponent pair (a, d) defining $f_{j-1}(x)$ by the two pairs $(-a, d)$ and $(a, (d + (m/p_j)) \bmod m)$ and then sorting the complete list of new pairs in increasing order by their second components, combining pairs that have like exponents. Inductively, we obtain that $f_j(x)$ has $\le 2^j N$ non-zero terms, with each coefficient $\le 2^j NH$ and each exponent $\le m$. Using the running time analysis for computing $\omega\big(g(x)\big)$, computing $\omega\big(f_{j-1}(x)\big)$ takes

$$\ll 2^s N \log(H+1) + 2^s N(s + \log N)\big(s + \log n + \log N\big)^{1+o(1)}$$

binary operations. Multiplying this estimate by s gives an upper bound on the total number of binary operations to perform Step A3.

The polynomial $f_s(x)$ either consists of an empty coefficient-exponent pair list or the list contains at least one pair. Step A4 therefore is a simple check to see which of these is the case and takes

$$\ll 2^s N\big(s + \log n + \log N + \log(H+1)\big)$$

binary operations, a bound on the bit-length of $f_s(x)$.

The result of the theorem follows. □

Proof of Theorem 1. Corollary 1 implies that we need only consider the possibility that $\Phi_m(x)|f(x)$ where each prime divisor of m is $\leq N$, the number of non-zero terms of $f(x)$. For each prime $p \leq N$, we consider

$$r(p) = \left[\frac{\log \deg f}{\log p}\right] + 1. \tag{2}$$

Observe that if $p^e|m$, then

$$\deg f(x) \geq \deg \Phi_m(x) = \phi(m) \geq \phi(p^e) = p^{e-1}(p-1) \geq p^{e-1}$$

so that $e \leq r(p)$. We make use of this notation for describing an algorithm for proving Theorem 1.

Algorithm B *(General Cyclotomic Factor Test)***:** Given $f(x) = \sum_{j=1}^{N} a_j x^{d_j} \in \mathbb{Z}[x]$ with $\deg f = n$, determine whether there is at least one m such that $\Phi_m(x)$ divides $f(x)$.

Step B1. *Determine Relevant Primes.* Compute the set $P = \{p_1, p_2, \ldots, p_r\}$ of all primes $\leq N$.

Step B2. *Obtain Exponent Bounds.* Compute $B_j = r(p_j)$ (defined by (2)) for $1 \leq j \leq r$.

Step B3. *Determine Relevant Elements.* Compute the subsets $\{q_1, q_2, \ldots, q_s\}$ of P for which

$$2 + \sum_{j=1}^{s} (q_j - 2) \leq N. \tag{3}$$

Let $\mathcal{Q}$ denote the set of all such subsets.

Step B4. *Compute Possible Cyclotomic Factors.* Construct a list of tuples

$$\big((q_1, e_1), (q_2, e_2), \ldots, (q_s, e_s)\big)$$

where $\{q_1, q_2, \ldots, q_s\} \in \mathcal{Q}$ and if $q_i = p_j$ then $1 \leq e_i \leq B_j$.

Step B5. *Check Divisibility.* For each $\big((q_1, e_1), \ldots, (q_s, e_s)\big)$ in Step B4, apply Algorithm A with $m = q_1^{e_1} q_2^{e_2} \cdots q_s^{e_s}$ to determine whether $\Phi_m(x)$ divides $f(x)$. If at least one such m exists, indicate that $f(x)$ has a cyclotomic factor. Otherwise, indicate that $f(x)$ has no cyclotomic factor.

Given the algorithm above, we need to justify the correctness of the algorithm and the appropriate running time. Corollary 1 implies that $f(x)$ is divisible by a cyclotomic polynomial if and only if $\Phi_m(x)|f(x)$ for some positive integer m such that the complete set of prime divisors of m is an element of $\mathcal{Q}$. As indicated after (2), if $p_j^e||m$, then $e \leq r(p_j) = B_j$. It follows that $f(x)$ is divisible by a cyclotomic polynomial if and only if $\Phi_m(x)|f(x)$ for some positive integer m considered in Step B5. Thus, the correctness of the algorithm is justified.

Next, we justify the bound on the running time indicated for the algorithm. The first two steps indicated in the algorithm can be estimated rather poorly without affecting this bound. In Step B1, the primes that are $\leq N$ are determined. A crude upper bound on the number of binary operations for this step is $\mathcal{O}(N^2)$. Note that r is determined by the condition $p_r \leq N < p_{r+1}$. Hence, by the Prime Number Theorem, $r \sim N/\log N$. Computing any particular B_j takes no more than $\mathcal{O}(\log^3 n)$ binary operations so that the running time for Step B2 is $\ll r \log^3 n \ll N \log^3 n/\log N$.

The running time for the algorithm is affected largely by the number of elements of $\mathcal{Q}$. From (3) and $r \sim N/\log N$, we deduce that

$$\sum_{j=1}^{s} q_j \leq (1 + o(1))N \tag{4}$$

as N tends to infinity. Using that $\sum_{p \leq z} p \sim z^2/(2 \log z)$, we obtain from (4) that

$$s \leq (2 + o(1))\sqrt{N/\log N}$$

(take $z = (1 + \varepsilon)\sqrt{N \log N}$ and use that $\pi(z) \sim z/\log z$). Let K denote this bound on s. Since there are r choices for each prime q_j, we deduce that

$$|\mathcal{Q}| \leq r^K \leq N^K = \exp\big((2 + o(1))\sqrt{N \log N}\big).$$

In Step B3, the elements of $\mathcal{Q}$ are determined. This can be done by considering increasing values of s beginning with $s = 1$ and determining those subsets of P of size s that belong to $\mathcal{Q}$. For each of the $\leq r^s$ subsets of P of size s, checking (3) takes $\ll s \log N$ binary operations. Once a value of s is obtained for which no

subsets of P of size s belong to $\mathcal{Q}$, the set $\mathcal{Q}$ will be determined and Step B3 ends. By the definition of K, there are no subsets of P of size $K+1$ in $\mathcal{Q}$. It follows that the number of binary operations needed for Step B3 is

$$\ll \sum_{s=1}^{K+1} r^s s \log N \ll r^{K+1} K \log N \ll \exp\big((2+o(1))\sqrt{N \log N}\big).$$

For Step B4, we observe that $B_1 \leq 1 + 2\log n$ and $B_j \leq 1 + \log n$ for $j > 1$. For each of the $\leq r^K$ elements $\{q_1, q_2, \ldots, q_s\}$ of $\mathcal{Q}$, we therefore form at most $2(1+\log n)^s \leq 2(1+\log n)^K$ tuples $\big((q_1, e_1), \ldots, (q_s, e_s)\big)$. It follows that there are

$$\ll r^K (1+\log n)^K \ll \exp\big(K(\log r + \log(1+\log n))\big)$$

such tuples. Note that we are interested in asymptotics as N (and, hence, n) tends to infinity so that, in particular, $\log(1+\log n) \sim \log\log n$. Forming each tuple $\big((q_1, e_1), \ldots, (q_s, e_s)\big)$ takes

$$\ll K(\log N + \log\log n)$$

binary operations. Therefore, we can use

$$\mathcal{O}\big(\exp\big((1+o(1))K(\log r + \log\log n)\big)\big)$$

as an upper bound on the running time for Step B4.

The running time for Step B5 is determined from the running time for Algorithm A as given by Theorem 3. Observe that we can take $M = N$ in Theorem 3 as N serves as a bound for every q_j. Also, $M = N \leq n$, $E \ll \log n$, and $s \leq K \ll \sqrt{N}$. Given the number of tuples considered in Step B4, the running time for Step B5 is

$$\ll 2^K N^{5/2}\big(\log^{2+o(1)} n + \log(H+1)\big) \exp\big((1+o(1))K(\log r + \log\log n)\big).$$

Using $r \sim N/\log N$ and $K = (2+o(1))\sqrt{N/\log N}$, the running time in Step B5 is bounded by

$$\ll \exp\big((2+o(1))\sqrt{N/\log N}(\log N + \log\log n)\big)\log(H+1)$$

as N tends to infinity. As this exceeds the bounds obtained for the running times in the previous steps of the algorithm, it also serves as a bound for the order of magnitude of the running time of the entire algorithm, completing the proof. □
