

## Mathematics 700 Homework

### Due Friday, October 18

**Problem 1.** This problem is to familiarize you with some properties of multiplication by diagonal matrices with are more or less obvious after seeing them. Let

$$D = \text{diag}(\lambda_1, \lambda_2, \dots, \lambda_n) = \begin{bmatrix} \lambda_1 & 0 & \cdots & 0 \\ 0 & \lambda_2 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & \lambda_n \end{bmatrix}.$$

(a) Let  $A$  be a matrix with  $n$  rows (and any number of columns)

$$A = \begin{bmatrix} A^1 \\ A^2 \\ \vdots \\ A^n \end{bmatrix}.$$

Then multiplying  $A$  on the left by  $D$  multiplies the rows of by  $\lambda_1, \lambda_2, \dots, \lambda_n$ . That is you are to show

$$DA = \begin{bmatrix} \lambda_1 A^1 \\ \lambda_2 A^2 \\ \vdots \\ \lambda_n A^n \end{bmatrix}.$$

(b) Likewise show that if  $B$  has  $n$  columns (and any number of rows)

$$B = [B_1, B_2, \dots, B_n]$$

then multiplying  $B$  on the right by  $D$  multiplies the columns by  $\lambda_1, \dots, \lambda_n$ . That is

$$BD = [\lambda_1 B_1, \lambda_2 B_2, \dots, \lambda_n B_n].$$

(c) Assume that  $\lambda_1, \lambda_2, \dots, \lambda_n$  are all distinct. Then find all  $n \times n$  matrices  $C$  which commute with  $D$ . That is all  $C$  so that  $CD = DC$ . □

Polynomials are going to play a larger and larger rôle in our understanding of matrices and linear operators. Let  $\mathbf{F}$  be our field of scalars. Then we use the standard notation  $\mathbf{F}[x]$  for the set of all polynomials in the indeterminate  $x$  over  $\mathbf{F}$ . That is  $p(x) \in \mathbf{F}[x]$  is an expression of the form

$$(1) \quad p(x) = a_0 + a_1x + a_2x^2 + \cdots + a_nx^n.$$

We add and multiply these by the rules you have been using for as long as you can remember. If  $A$  is a square matrix and  $p(x) \in \mathbf{F}[x]$  is given by (1) then we can define  $p(A)$  to be  $p(x)$  evaluated at  $x = A$ . That is

$$p(A) = a_0I + a_1A + a_2A^2 + \cdots + a_nA^n$$

where  $I$  is the identity matrix. By convention  $A^0 = I$  for all matrices. Likewise if  $T: V \rightarrow V$  is a linear operator on a vector space  $V$  then we define

$$p(T) = a_0I + a_1T + a_2T^2 + \cdots + a_nT^n$$

where this time  $I$  is the identity map on  $V$  and again  $T^0 = I$  by convention.

As an example let

$$A = \begin{bmatrix} 1 & -2 \\ 3 & 5 \end{bmatrix}$$

and  $p(x) = 2x^2 - 4x + 3$ . Then

$$\begin{aligned} p(A) &= 2A^2 - 4A + 3I \\ &= 2 \begin{bmatrix} 1 & -2 \\ 3 & 5 \end{bmatrix}^2 - 4 \begin{bmatrix} 1 & -2 \\ 3 & 5 \end{bmatrix} + 3 \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \\ &= 2 \begin{bmatrix} -5 & -12 \\ 18 & 19 \end{bmatrix} + \begin{bmatrix} -4 & 8 \\ -12 & -20 \end{bmatrix} + \begin{bmatrix} 3 & 0 \\ 0 & 3 \end{bmatrix} \\ &= \begin{bmatrix} -10 & -24 \\ 36 & 38 \end{bmatrix} + \begin{bmatrix} -1 & 8 \\ -12 & -17 \end{bmatrix} \\ &= \begin{bmatrix} -11 & -16 \\ 24 & 21 \end{bmatrix}. \end{aligned}$$

**Problem 2.** Let  $D = \text{diag}(\lambda_1, \lambda_2, \dots, \lambda_n)$ .

(a) Show  $p(D) = \text{diag}(p(\lambda_1), p(\lambda_2), \dots, p(\lambda_n))$ .

(b) If  $f(x) = (x - \lambda_1)(x - \lambda_2) \cdots (x - \lambda_n)$ , then what is  $f(D)$ ? □

**Problem 3.** Let  $A, B \in M_{n \times n}(\mathbf{F})$  and assume that  $A$  and  $B$  commute (that is  $AB = BA$ ). Let  $p(x) \in \mathbf{F}[x]$  be a polynomial. Show that  $p(A)$  and  $B$  commute. Let  $p(x), q(x) \in \mathbf{F}[x]$ . Then is it true that  $p(A)$  and  $q(B)$  commute? □

**Problem 4.** Let  $A \in M_{n \times n}(\mathbf{F})$  be a square matrix. Then show that there is a nonzero polynomial  $p(x) \in \mathbf{F}[x]$  of degree  $\leq n^2 + 1$  so that  $p(A) = 0$ . (We will later do much better and show  $p(x)$  can be chosen with  $\deg p(x) \leq n$ . A first step in this direction is Problem 6 below.) HINT: Consider  $\{I, A, A^2, \dots, A^n, A^{n^2+1}\}$  and use that  $\dim M_{n \times n}(\mathbf{F}) = n^2$ . □

**Problem 5.** Let  $A, B \in M_{n \times n}(\mathbf{F})$  be similar. Then show that for any polynomial  $p(x) \in \mathbf{F}[x]$  that  $p(A)$  and  $p(B)$  are similar. Specifically show that if  $B = P^{-1}AP$  then  $p(B) = P^{-1}p(A)P$ . □

**Problem 6.** Let  $A \in M_{n \times n}(\mathbf{F})$  be a square matrix and assume that the roots  $\lambda_1, \lambda_2, \dots, \lambda_n$  of the characteristic polynomial  $\text{char}_A(x) = \det(xI - A)$  are distinct. Let  $f(x)$  be the polynomial

$$f(x) = (x - \lambda_1)(x - \lambda_2) \cdots (x - \lambda_n).$$

(A little thought will should convince you that  $f(x) = \text{char}_A(x)$ , but this is not needed to do the problem.) Then show  $f(A) = 0$ . HINT: Recall that if the roots of  $\text{char}_A(x)$  are distinct, then  $A$  is diagonalizable. Now use Problems 2 (b) and 5. □

**Problem 7.** Let  $T: V \rightarrow V$  be a linear map and assume  $\lambda$  is an eigenvalue of  $T$ . This show that for any polynomial  $p(x) \in \mathbf{F}[x]$  that  $p(\lambda)$  is an eigenvalue of  $p(T)$ . HINT: Consider the special case of  $p(x) = x^2 + 3$ . Let  $v \in V$  be an eigenvector for  $\lambda$ , that is  $v \neq 0$  and  $Tv = \lambda v$ . Then  $p(T)v = (T^2 + 3I)v = TTv + 3Iv = T\lambda v + 3v = \lambda Tv + 3v = \lambda\lambda v + 3v = (\lambda^2 + 3)v = p(\lambda)v$ .  $\square$

Finally here is a problem to review on quotient spaces.

**Problem 8.** Let  $V$  be a vector space and  $W \subset V$  a subspace. Let  $T: V \rightarrow V$  be linear and assume that  $W$  is invariant under  $T$ . (This means that  $T[W] \subseteq W$  or what is the same thing if  $v \in W$  then  $Tv \in W$ . For any  $v \in V$  let  $[v]$  be the coset of  $W$  in  $V$ . (That is  $[v] = v + W = \{u \in V : v - u \in W\}$ . As before  $[v] = [u]$  if and only if  $v - u \in W$ .) Define  $\widehat{T}: V/W \rightarrow V/W$  by

$$\widehat{T}[v] = [Tv].$$

- (a) Show that  $\widehat{T}$  is well defined. That is show that if  $[v] = [u]$ , then  $[Tv] = [Tu]$ .
- (b) Show  $\widehat{T}$  is linear.
- (c) If  $p(x) \in \mathbf{F}[x]$  show that  $W$  is also invariant under  $p(T)$  and that  $p(\widehat{T}) = \widehat{p(T)}$ .
