

**Problem 5 in Section 2.2.** Consider the Differential Equation  $\frac{dx}{dt} = x^2 - 4$ .

- What are the equilibrium solutions of this autonomous Differential Equation?
- Draw the phase diagram for this Differential Equation.
- Are the equilibrium solutions of this Differential Equation stable or unstable?
- Sketch the solution of the Initial Value problem

$$\frac{dx}{dt} = x^2 - 4 \quad x(0) = x_0, \quad (6)$$

for a few choices of  $x_0$ .

- Solve the Initial Value Problem (6). (Be sure that your answer is in the form  $x$  is equal to some function of  $t$ .)

We see that  $x^2 - 4 = (x - 2)(x + 2)$ ; thus  $x^2 - 4$  is equal to zero when  $x = 2$  or  $x = -2$ . We conclude that  $x = 2$  and  $x = -2$  are equilibrium solutions of the given Differential Equation. We see that

- $(x - 2)(x + 2)$  is positive for  $2 < x$ ;
- $(x - 2)(x + 2)$  is negative for  $-2 < x < 2$ ; and
- $(x - 2)(x + 2)$  is positive for  $x < -2$ .

(The phase diagram is on the last page of this solution.) We conclude that

- if  $2 < x_0$ , then the graph of  $x = x(t)$  increases away from 2 as  $t$  goes to  $\infty$ ;
- if  $-2 < x_0 < 2$ , then the graph of  $x = x(t)$  decreases away from 2 and towards  $-2$  as  $t$  goes to  $\infty$ ; and
- if  $x_0 < -2$ , then the graph of  $x = x(t)$  increases towards  $-2$  as  $t$  goes to  $\infty$ .

In other words,

The function  $x = 2$  is an unstable equilibrium solution of  $\frac{dx}{dt} = x^2 - 4$  and the function  $x = -2$  is a stable equilibrium solution of  $\frac{dx}{dt} = x^2 - 4$ .

On the last page of this solution, we sketched five solutions of the Initial Value Problem

$$\frac{dx}{dt} = x^2 - 4 \quad x(0) = x_0.$$

In one solution  $x_0$  is bigger than 2; in one solution  $x_0$  is equal to 2; in one solution  $x_0$  is between  $-2$  and  $2$ ; in one solution  $x_0$  is equal to  $-2$ ; and in one solution  $x_0$  is less than  $-2$ .

We solve  $\frac{dx}{dt} = x^2 - 4$  by separating the variables and integrating:

$$\int \frac{dx}{x^2 - 4} = \int dt. \quad (7)$$

Use the method of partial fractions:

$$\frac{1}{(x-2)(x+2)} = \frac{A}{x-2} + \frac{B}{x+2}.$$

Multiply both sides by  $(x-2)(x+2)$ :

$$1 = A(x+2) + B(x-2).$$

Plug in  $x = 2$  to see that  $A = \frac{1}{4}$ . Plug in  $x = -2$  to see that  $B = -\frac{1}{4}$ . Thus,

$$\frac{1}{(x-2)(x+2)} = \frac{1}{4} \left( \frac{1}{x-2} - \frac{1}{x+2} \right).$$

The integral (7) is

$$\frac{1}{4} \int \left( \frac{1}{x-2} - \frac{1}{x+2} \right) dx = t + C$$

$$\frac{1}{4} (\ln|x-2| - \ln|x+2|) = t + C$$

$$(\ln|x-2| - \ln|x+2|) = 4t + 4C$$

Exponentiate:

$$\frac{|x-2|}{|x+2|} = e^{4C} e^{4t}$$

$$\frac{x-2}{x+2} = \pm e^{4C} e^{4t}$$

Let  $K$  be the constant  $\pm e^{4C}$ .

$$\frac{x-2}{x+2} = K e^{4t}.$$

Maybe this is a good time to find  $K$ . Plug  $t = 0$  into the most recent equation to learn

$$\frac{x_0 - 2}{x_0 + 2} = K. \quad (8)$$

(We will keep writing  $K$  for now. Eventually, we will insert this value for  $K$  into our answer.) We want to solve for  $x$ . Multiply both sides by  $x+2$ :

$$x - 2 = K e^{4t} (x + 2).$$

Subtract  $Ke^{4t}x$  from both sides and add 2 to both sides:

$$x - Ke^{4t}x = 2Ke^{4t} + 2.$$

Factor an  $x$  out of both terms on the left:

$$x(1 - Ke^{4t}) = 2Ke^{4t} + 2.$$

Divide both sides by  $1 - Ke^{4t}$

$$x = \frac{2Ke^{4t} + 2}{1 - Ke^{4t}}$$

Insert (8) into our answer:

$$x = \frac{2\left(\frac{x_0-2}{x_0+2}\right)e^{4t} + 2}{1 - \left(\frac{x_0-2}{x_0+2}\right)e^{4t}}.$$

Factor a 2 out of both terms in the numerator. Multiply the top and the bottom both by  $x_0 + 2$ :

$$x = \frac{2((x_0 - 2)e^{4t} + x_0 + 2)}{x_0 + 2 - (x_0 - 2)e^{4t}}.$$

**Check.** We plug the proposed answer into  $\frac{dx}{dt} - x^2 + 4$ . We see the expression ultimately simplifies to become 0. At any rate, if  $x = \frac{2((x_0-2)e^{4t}+x_0+2)}{x_0+2-(x_0-2)e^{4t}}$ , then

$$\begin{aligned} & \frac{dx}{dt} - x^2 + 4 \\ = & \begin{cases} \frac{2((x_0-2)e^{4t}+x_0+2)(-1)(-4(x_0-2)e^{4t})}{(x_0+2-(x_0-2)e^{4t})^2} + \frac{8(x_0-2)e^{4t}}{(x_0+2-(x_0-2)e^{4t})} \\ - \left(\frac{2((x_0-2)e^{4t}+x_0+2)}{x_0+2-(x_0-2)e^{4t}}\right)^2 \\ + 4 \end{cases} \\ = & \frac{\begin{cases} +2((x_0-2)e^{4t} + x_0 + 2)(-1)(-4(x_0-2)e^{4t}) \\ + (8(x_0-2)e^{4t})(x_0+2-(x_0-2)e^{4t}) \\ - \left(2((x_0-2)e^{4t} + x_0 + 2)\right)^2 \\ + 4(x_0+2-(x_0-2)e^{4t})^2 \end{cases}}{(x_0+2-(x_0-2)e^{4t})^2} \\ = & \frac{\begin{cases} +8(x_0-2)^2e^{8t} + 8(x_0+2)(x_0-2)e^{4t} \\ + 8(x_0+2)(x_0-2)e^{4t} - 8(x_0-2)^2e^{8t} \\ - 4(x_0-2)^2e^{8t} - 8(x_0-2)(x_0+2)e^{4t} - 4(x_0-2)^2 \\ + 4(x_0+2)^2 - 8(x_0+2)(x_0-2)e^{4t} + 4(x_0-2)^2e^{8t} \end{cases}}{(x_0+2-(x_0-2)e^{4t})^2} \end{aligned}$$

The numerator adds to zero. Our proposed solution is correct.

The pictures are on the next page.
